tially abandoned by him. Rayan went to private sector around 1992, and ZMailer development was essen-

Since then, yours truly has been hacking at it developing all kinds of extensions for modern Internet email.

Introduction to the Terminology

In the 1970'es the *Institute for Federal Information Processing* defined terminology for then a new thing: email. The terminology was made more popular by X.400 standard from 1984

MTA: Mail Transfer Agent – program to move mail from one system to other.

ery to local message store/driving program agents/whatnot. **MDA/LDA:** A latter addition; Message/Local Delivery Agent – program (subsystem) doing deliv-

database MS: Message Store – Standard UNIX mailbox, or something way more complicated like a

compose email, and submit to the care of the MTA **MUA:** Mail User Agent – program which user uses to pick their email from the MS, read them,

unlike MTA, compare with vacation(1)) content, usually driven directly by the MTA without the message ever going via MS. (E.g. quite **UA:** A generic X.400 term for the User Agent – basically software entity acting on message

ESMTP RFC's

ZMailer's *smtpserver* subsystem implements a rich set of enhanced SMTP features defined over the last 10 or so years.

At the same time it aims to be lightweight, fast protocol receiver with ability to quickly verify incoming protocol stream syntax conformance, but it can also be configured to behave sloppily in this regard.

ZMailer subsystems: "smtpserver" (3)

system performance for no practically usefull thing. derneath itself, however that is seriously heavy-weight thing, and really taxes The smtpserver can do interactive routing analysis of MAIL FROM: and RCPT TO: phase envelope addresses by running a router process synchronously un-

local database files giving the system an idea of which domains are local, and A more usefull approach is simply to do SMTP MX/A routing rules analysis of which are rules for finding which domains are our customers source and destination envelope addresses, with some control rules from a few

ZMailer subsystems: "smtpserver" (4)

sis program for each received message synchronous for the message reception. There are also some experimental hooks to run external message content analy-

with OpenSSL library. ZMailer has been used as one of comparison benchmarks for sendmail(8)'s new STARTTLS functionality. A non-experimental thing is STARTTLS encrypted application mode implemented

when using plaintext password authentication for email sending. Session encryption was mainly implemented for giving some peace of mind

ZMailer subsystems: "smtpserver" (5)

sage reception, the world seems to be full of crappy systems whose coders have done several basic mistakes: As much as I would like to run things with strict protocol adherence also at mes-

- groak when receiving such replies SMTP protocol replies can be multiline all the time (RFC 821 Annex E), many softwares
- entire line(s) at one go.) does not do proper line segment collection into lines, and instead expects the receive return SMTP protocol replies can arrive in multiple TCP segments (some MS platform software

with PIPELINING optimization.) ZMailer's smtpserver defaults to one-line replies sent out in one block. (Except

ZMailer subsystems: "smtpserver" (6)

"The theory of SMTP reply codes" (RFC 821 Annex E) tells that if exact encounter unexpected reply code. should guide its interpretation. Many systems barf completely when they code is not known (e.g. new non-821-listed ones are invented), the first digit

ZMailer's smtpserver tries to use only "valid at the place" reply codes.

ZMailer subsystems: "s*mtpserver*" (7)

tory < and > angle brackets. still lots of clients are sending "MAIL FROM: user@domain" without the manda-RFC 821 has quite clear BNF production rules for the protocol syntax, and

col. (The sendmail(8) is the archetype of "sloppy by default" SMTP receive protocol implementation, and also the reason for these utterly sloppy client ZMailer's smtpserver can be configured to accept such Sloppy input protoimplementations.)

ZMailer subsystems: "smtpserver" (8)

Many SMTP client systems can't report accurately what protocol command to the server. they sent out when reporting to user an error they encountered while talking

in the diagnostic report. ZMailer's smtpserver attempts to copy the MAIL FROM/RCPT TO address

ZMailer subsystems: "smtpserver" (9)

Many SMTP client systems give up the entire message when in a multiseries reply. recipient mail even one of the RCPT TO addresses is yielding 400 or 500

things like "ccMail". Many, if not all, user agents have this problem, as seem to have "MTA" class ZMailer does not yet have a solution for this kind of SMTP client stupidity.

```

smtpserver policy-db construction rules

At the end of this is actually the default boiler-plate file from the distribution pretty much as is.

In addition to that, policy-builder.sh script adds a set of other things before policy filter is ready

```
DB/smtp-policy.spam.manual ('= _bulk_mail')
                                                                             DB/localnames
                                                                                                DB/smtp-policy.src
                    DB/smtp-policy.spam
                                       DB/smtp-policy.mx
                                                          DB/smtp-policy.relay
                                                             _bulk_mail')
                                                           _full_rights')
                                      _relaytarget')
                                                                            _local_names')
                                                                                                 The boilerplate
```

If you want, you can modify your boiler plate as well as your installed policy-builder.sh script. (Doing 'make install' will overwrite policy-builder.sh, but not smtp-policy.src)

See file "doc/guides/smtp-policy" for more info.

ZMailer subsystems: "router"

- about the router program tasks
- about router configuration mechanisms
- about resource consumption, and its control
- about the router script language

ZMailer subsystems: "router" (2)

Tasks of the router subsystem are:

- Picking tasks for processing from multiple input queues.
- Producing analysis on what to do with given input addresses (i.e. "routing").
- Producing scheduler + transport agent control information regarding the message

ZMailer subsystems: "router" (3)

dling lots and lots of email over long periods of time. Resource spenditure is limited at the router by having long-living processes han-

others get only one workers. The main input queue area can get more than one processing process, The *router* processes are running as one taskmaster ("scheduler"), and a farm of

achieved with LISP-like memory management strategies inside the router. Each process aims to have as small memory footprint as possible, which is

ZMailer subsystems: "router" (4)

the /bin/sh a.k.a. The Shell. The router is configured with a script language which greatly resembles that of

sequencer starts to call "process" entrypoint with taskfile name as a parameter. picking more configuration scripts in given order. Once all are loaded, the task The *router* picks file "router.cf" from a well-known location, and continues then
